Section 1
Introduction

1.1 Purpose and Scope

This module specifies the Orbit Data File (ODF) format of the radio metric data from the Deep Space Network (DSN). The content and formats of the ODF data blocks generated by the Multi-Mission Navigation (MMNAV) Radio Metric Data Conditioning Team (RMDCT), and either transmitted electronically or provided on magnetic tape by the NAV, are herein defined.

1.2 Revision and Control

Revisions or changes to information herein presented may be initiated in accordance with the procedures in Section 1 of this document.

Section 2
General Information

The data will be stored by the MMNAV RMDCT for transmission.

Figure 2-1 shows the data flow from the DSN Signal Processing Center (SPC) to the Remote Mission Operations Center (RMOC) for the transmitted data, and for data provided electronically or on magnetic tape to JPL Projects.

When the ODFs are to be transmitted to an RMOC, the Ground Communications Facility (GCF) is assumed to be transparent. The data shall be formatted into 1200-bit or 4800-bit data blocks and transmitted to the user via the Digital Communications Subsystem (GDC) of the GCF.

SFOC-NAV-TRK-2-18

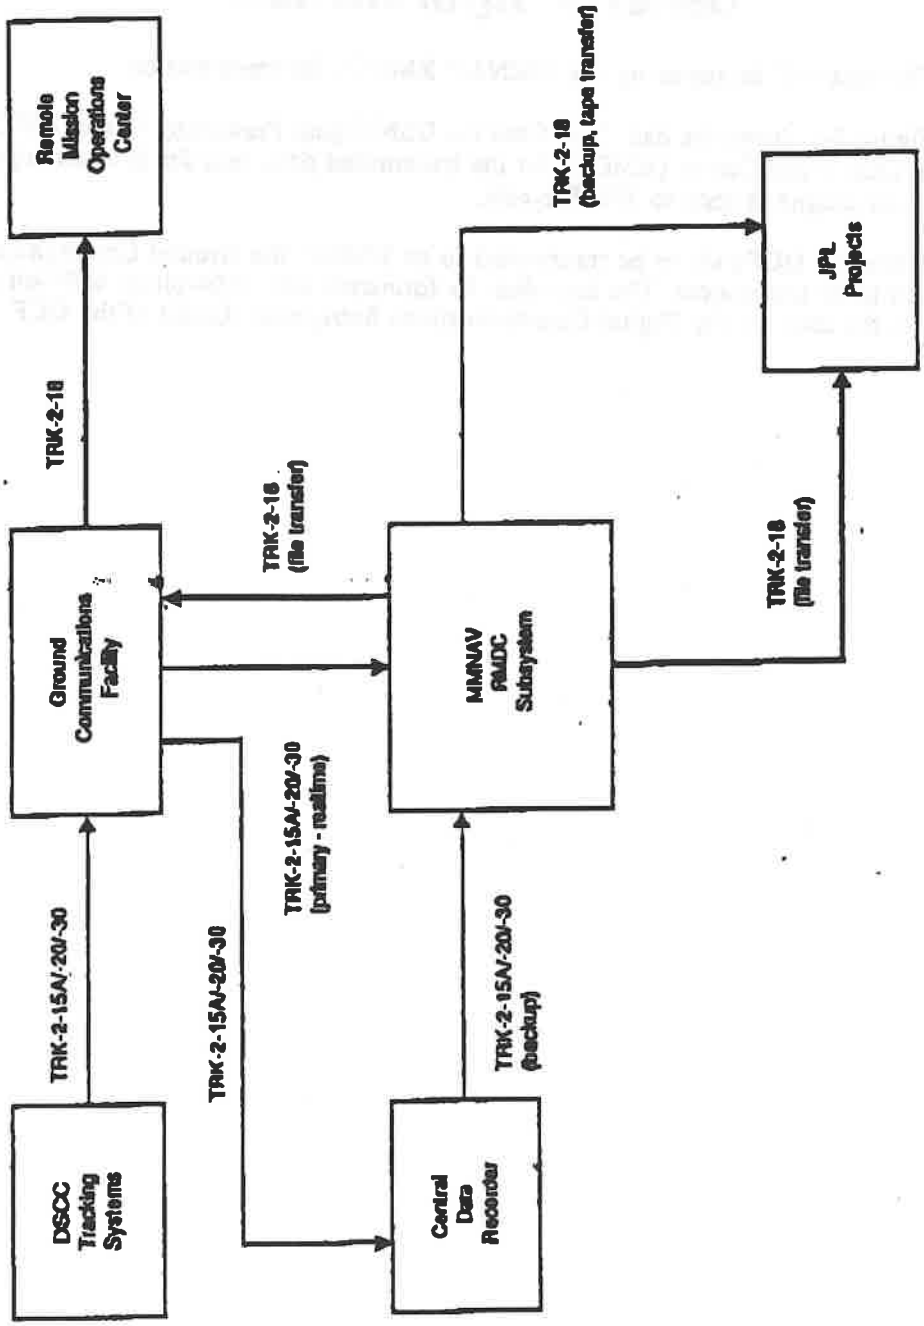

Figure 2-1. Data Flow for Orbit Data File Interface

Section 3
Data Format and Fields

3.1 GCF Data Blocks

The ODF data blocks are standard 1200-bit or 4800-bit data blocks that contain radio metric data that have been reformatted from the 820-13, TRK-2-15A, TRK-2-20, or TRK-2-30 formats. The first 120 bits of the block form the block header and provide information common to all data in the block. The Block Information Field (BIF) consists of 1032 bits for a 1200-bit block and contains three packets (each consisting of nine 32-bit words) described in Tables 3-1 through 3-8. The BIF for the 4800-bit block consists of 4632 bits and contains 16 packets of data. The last 48 bits of the data block contain the GCF error detection and correction data, the Error Status Code (ESC) and the Error Polynomial Code (EPC). The ODF blocks will be ordered by block header time and date. Detailed descriptions of the header, BIF, and block ending are provided in the following paragraphs:

WORD 1 THRU WORD 8, BIT 8

Standard DSN Block Header as described in module OPS-6-8 of this document, with the following code assignments:

Source Code = AF_{16} (257_8 - DSN NAV)

UDT Code = 15_{16} (025_8)

DDT Code = 14_{16} (024_8)

WORD 8, BITS 9 THRU 16

Set to zeros

WORD 9 THRU WORD 72/WORD 297

BIF - ODF data with the following constraints:

(1) Each complete ODF will span several blocks.

(2) A complete ODF will consist of the following data presented in order of transmission:

a) File Label group - one per ODF (Tables 3-1a and 3-1b); required

b) Identifier group - one per ODF (Tables 3-2a and 3-2b); required

c) Orbit Data group - multiple records, time ordered (Tables 3-3a and 3-3b); required

d) Ramp groups - one group for each DSS, multiple records, time ordered (Tables 3-4a and 3-4b); optional

e) Clock Offsets group - multiple records, time ordered (Tables 3-5a and 3-5b); optional

f) Uplink Phase groups - one group for each DSS, multiple records, time ordered (Tables 3-6a and 3-6b); optional

g) Data Summary group - multiple records, ordered by station, band, and data type (Tables 3-7a and 3-7b); optional

h) End-of-File group - one per ODF (Table 3-8); required

(3) Each ODF consists of the radio metric data for one spacecraft, zero or more quasars, and one or more stations.

(4) Character data are 8-bit ASCII-equivalent integer values.

(5) Times, except as noted, are given as seconds past zero hours UTC, of January 1, 1950.

(6) For 1200-bit blocks, Words 63 through 72 will always contain filler (repetitive 1000_2). For 4800-bit blocks, Word 297 will always contain filler. Unused portions of any BIF will contain filler.

(7) The ODF data words are 32 bits in length.

(8) The 5th and 6th data words of an ODF packet/record are always zero (0) for a group header record, and are always non-zero for a data record.

(9) The parameter field pack format conventions used herein are as follows:

Ix = unsigned integer, x bits in length
Sx = signed integer, x bits in length, two's complement

(10) Most data parameters will be provided as binary integers; two's complement will be used for all fields that may have negative values.

(11) Single-bit status parameters will be set to one (1) for no, bad, off, out of tolerance, etc.; and will be set to zero (0) for yes, good, on, in tolerance, etc.

WORD 73 THRU WORD 75/WORD 298 THRU WORD 300

Standard DSN block ending as described in module OPS-6-8 of this document.

3.2 *Electronic and Magnetic Tape Interface*

The ODF data are provided in disk files or on unlabeled, 9-track, 1600-bits/in. magnetic tapes. Each ODF block (or physical record) consists of 2016 32-bit words, for a total length of 64,512 bits. Each block contains 224 9-word (288-bit) logical records. These records are described in Tables 3-1 through 3-8.

Appendix A
Doppler and Range Observables

Doppler and range observables, rather than the actual measurements made at the Deep Space Stations, are provided in the ODF Orbit Data Group (see Table 3b, items 4 and 5).

The Doppler observable (in Hertz) is computed according to the following equation. The time tag is at the mid-point of the compression interval, t_i to t_j.

$$Observable = \frac{B}{|B|} \cdot \left[\frac{(N_j - N_i)}{(t_j - t_i)} - |F_b \cdot K + B| \right]$$

where:

B	= Bias placed on receiver
N_i	= Doppler count at time t_i
N_j	= Doppler count at time t_j
t_i	= start time of interval
t_j	= end time of interval
F_b	= frequency bias
K	= 1 for S-band receivers (Table 3b, Item 11)
	= 11/3 for X-band receivers
	= 176/27 for Ku-band receivers
	= 209/15 for Ka-band receivers

NOTE: Future spacecraft transponders may require different turnaround ratios (e.g., K may vary).

$$F_b = \frac{X_1}{X_2} \cdot (X_3 \cdot F_r + X_4) - F_{SC} + R_3 \qquad \textit{for 1-way Doppler}$$

$$F_b = \frac{X_1}{X_2} \cdot (X_3 \cdot F_r + X_4) - \frac{T_1}{T_2} \cdot (T_3 \cdot F_t + T_4) \qquad \textit{for all other Doppler}$$

where:

F_r	= Receiver (VCO) frequency at time t_r
F_{SC}	= Spacecraft (beacon) frequency
F_t	= Transmitter frequency at time $t_{r\text{-}RTLT}$
R_3	= 0 for S-band receivers
	= 0 for X-band receivers
	= 0 for Ku-band receivers
	= 0 for Ka-band receivers

T_1 = 240 for S-band transmitters (Table 3b, Item 12)
= 240 for X-band transmitters
= 142 for Ku-band transmitters
= 14 for Ka-band transmitters

T_2 = 221 for S-band transmitters
= 749 for X-band transmitters
= 153 for Ku-band transmitters
= 15 for Ka-band transmitters

T_3 = 96 for S-band transmitters
= 32 for X-band transmitters
= 1000 for Ku-band transmitters
= 1000 for Ka-band transmitters

T_4 = 0 for S-band transmitters
= 6,500,000,000 for X-band transmitters
= -7,000,000,000 for Ku-band transmitters
= 10,000,000,000 for Ka-band transmitters

X_1 to X_4 have the same values as T_1 to T_4 but are dependent on the exciter band (Table 3b, Item 13).

NOTE: When the reference frequency (Table 3b, items 18 and 19) are provided at sky level, T_3 and X_3 are 1 for all bands, and T_4 and X_4 are 0 for all bands.

For range data, the observable is computed as follows:

Observable = R - C + Z - S

where:

R = range measurement
C = Station delay calibration
Z = Z correction
S = Spacecraft delay
